Machine learning algorithms use parameters that are based on training data—a subset of data that represents the larger set. As the training data expands to represent the world more realistically, the algorithm calculates more accurate results. Different algorithms analyze data in different ways.

Such algorithms dig deep into the text and find the stuff that points out at the attitude towards the product in general or its specific element. In other words, opinion mining and sentiment analysis mean an opportunity to explore the mindset of the audience members and study the state of the product from the opposite point of view.

Each year, two or three students from a local university spend the summer building algorithms and bots. Not all of these efforts succeed, but the company has begun implementing at least half a dozen solutions developed by the interns. Similar programs will be critical to attracting talent that can lead an increasingly automated finance function.

Clustering or cluster analysis is an unsupervised learning problem. It is often used as a data analysis technique for discovering interesting patterns in data, such as groups of customers based on their behavior. There are many clustering algorithms to choose from and no single best clustering algorithm for all cases. Instead, it is a good idea to explore a range of clustering

A Spanning Tree (ST) of a connected undirected weighted graph  $G$  is a subgraph of  $G$  that is a tree and connects (spans) all vertices of  $G$ . A graph  $G$  can have multiple STs, each with different total weight (the sum of edge weights in the ST). A Min(imum) Spanning Tree (MST) of  $G$  is an ST of  $G$  that has the smallest total weight among the various STs.
